Qudits are one system with d named states

Definition

A qudit wire represents a d -dimensional space with computational basis

$$|0\rangle, |1\rangle, \dots, |d-1\rangle.$$

An n -wire circuit represents a unitary on $(\mathbb{C}^d)^{\otimes n}$.

Qudit platforms

- ▶ ion levels: trapped-ion qudits ($d \leq 7$)
[Ringbauer 22] [Hrmo 23]
- ▶ photonic modes: integrated ququart processors [Chi 22]
- ▶ transmon levels: qutrit/ququart control
[IBM] [Fischer 23]
- ▶ bosonic modes: cat-code systems, related but not qudits [Alice & Bob]

Why qudits? More structure per wire

Compression example

Packing two qubits into one ququart turns the branch 11 into the value $A = 3$, and the target pair 01, 10 into ququart levels 1, 2.

Circuit-level use cases

wire compression

temporary levels

pack binary data into higher-dimensional wires [Litteken 23]

store intermediate values during Toffoli decompositions [Gokhale 19]
[Nikolaeva 23]

One-qudit universality comes from two-level gates

Embedding a 2×2 unitary

$$U = \begin{pmatrix} u_{00} & u_{01} \\ u_{10} & u_{11} \end{pmatrix}.$$

$U^{(i,i+1)}$ is the identity except on adjacent rows and columns $i, i+1$:

$$U^{(i,i+1)} = \begin{bmatrix} I & & & \\ & u_{00} & u_{01} & \\ & u_{10} & u_{11} & \\ & & & I \end{bmatrix}$$

rows and columns ordered as $\dots, i, i+1, \dots$

One-qudit synthesis

On the active two-level subspace:

$$P_0(\theta) = \begin{bmatrix} e^{i\theta} & 0 \\ 0 & 1 \end{bmatrix},$$

$$P_1(\theta) = \begin{bmatrix} 1 & 0 \\ 0 & e^{i\theta} \end{bmatrix}.$$

Euler angles write any $U(2)$ operation as a product of

$$P_0(\alpha), P_1(\beta), H.$$

Adjacent two-level embeddings generate $U(d)$. [Nielsen–Chuang] [Clements 16]

One entangling gate gives n -qudit universality

Entangling control

A value-control is a direct-sum branch.

For $d = 4$,

$$\text{ctrl}_2(U) = I \oplus I \oplus U \oplus I.$$

active branch $k = 2$

control-basis blocks

0	I			
1		I		
2			U	
3				I

$\text{diag}(I, I, U, I)$

Universal gate set $\mathcal{G}_d$ [Brylinski–Brylinski 02]

$$\mathcal{L}_d = \{P_k(\theta), H^{(i,j)}\},$$

$$\mathcal{G}_d = \mathcal{L}_d \cup \{\text{ctrl}_1(P_1(\theta))\},$$

$$\langle \mathcal{G}_d \rangle = U(d^n).$$

one-qudit

one-qudit

entangling

What is a complete presentation?

Definition

A presentation is a gate signature Σ together with equations $\mathcal{R}$, closed under circuit contexts.

$$\mathcal{R} \vdash C = D$$

means that C can be rewritten to D by local rule applications.

Soundness: derivations preserve semantics.

Completeness: equal semantics give a derivation.

Example

Two adjacent H gates cancel; the same local rewrite is allowed inside any circuit context.

$$\text{---} \boxed{H} \boxed{H} \text{---} \xrightarrow{\mathcal{R}} \text{---}$$

Compressing four basis states into one ququart

Basis encoding

$$\mathbb{C}^2 \otimes \mathbb{C}^2 \stackrel{\text{enc}}{\cong} \mathbb{C}^4, \quad |a_1 a_0\rangle \mapsto |2a_1 + a_0\rangle$$

Compression of 4 basis states

$$\text{Compr}(D \circ C) = \text{Compr}(D) \circ \text{Compr}(C),$$

$$\text{Compr}(\text{ctrl}_1(\text{ctrl}_1(U))) = \text{ctrl}_3(\text{Compr}(U)),$$

$$\text{Compr}(\text{ctrl}_1(X)) = X^{(2,3)},$$

$$\text{Compr}(\sigma \circ \text{ctrl}_1(H) \circ \sigma) = H^{(1,3)}.$$

△ This function here is partially defined.

A PRO formalizes circuit composition

Definition

A **PRO** is a strict monoidal category $\mathcal{P}$ with objects $\mathbb{N}$, tensor $m \otimes n = m + n$, and unit 0.

Read n as n **wires**; a morphism $C : n \rightarrow m$ as a circuit with n inputs and m outputs.

A PROP makes wire permutations structural

Definition

A **PROP** is a PRO with symmetries

$$\sigma_{m,n} : m + n \rightarrow n + m.$$

Diagrammatically, wires may be permuted as structural language.

These are extra **symmetry laws**, on top of the PRO laws from the previous slide.

$$\text{Unit: } \sigma_{0,n} = \text{id}_n = \sigma_{n,0}.$$

$$\sigma_{m,n} : m + n \rightarrow n + m$$

involution

$$\sigma_{n,m} \circ \sigma_{m,n} = \text{id}_{m+n}$$

naturality

$$\sigma \circ (f \otimes \text{id}) = (\text{id} \otimes f) \circ \sigma$$

A controlled PROP adds one control constructor

Definition

A **control functor** is an operation $\text{ctrl} : \mathcal{P}_{\text{endo}} \rightarrow \mathcal{P}_{\text{endo}}$ with $\text{ctrl}(n) = 1 + n$: it adds one chosen control wire.

* $\mathcal{P}_{\text{endo}}$: all circuits $n \rightarrow n$.

A polycontrolled PROP adds one constructor per value

Definition

A d -ary **polycontrolled PROP** is a PROP equipped with control functors

$$(\text{ctrl}_k : \mathcal{P}_{\text{endo}} \rightarrow \mathcal{P}_{\text{endo}})_{k \in [d]}.$$

Support-sensitivity

$$\begin{aligned} \text{supp}(f) &\subseteq [d]^n, \\ \text{supp}(\text{ctrl}_k(f)) &= \{k\} \times \text{supp}(f). \end{aligned}$$

Disjoint supports commute.

compatibility

$$\begin{aligned} &\text{ctrl}_a(\text{ctrl}_b(f)) \circ (\sigma_{1,1} \otimes \text{id}_n) \\ &= (\sigma_{1,1} \otimes \text{id}_n) \circ \text{ctrl}_b(\text{ctrl}_a(f)) \end{aligned}$$

commutativity ($a \neq b$)

$$\begin{aligned} &\text{ctrl}_a(f) \circ \text{ctrl}_b(g) \\ &= \text{ctrl}_b(g) \circ \text{ctrl}_a(f) \end{aligned}$$

exhaustivity

$$\begin{aligned} &\text{ctrl}_0(f) \circ \cdots \circ \text{ctrl}_{d-1}(f) \\ &= \text{id}_1 \otimes f \end{aligned}$$

Several ways to prove completeness

Normal forms

$$C \xLeftrightarrow[\text{unique}] N(U) \xLeftrightarrow D$$

- + canonical representative
- + can become an algorithm
- hard to design for rich syntax
- must prove actual normalization

[Selinger 15] [Li et al. 26]

Group presentation

$$\langle G \mid R \rangle \cong \text{Im}[\![-]\!]$$

- + proves generators and relations
- + good for discrete fragments
- relation sets can explode
- less natural with real parameters

[Bian–Selinger 22] & [23]

Transfer

- + reuses a complete calculus
- + isolates E, D , and mimicry
- expressivity must match
- auxiliary rules must decode

[Clément et al. 22]

Completeness is transferred by translation

Translation checks

E preserves semantics, $D(E(C)) = C$ is derivable, and each LOPP proof step must mimic inside QC_d .

$\triangle$ LOPP uses $\oplus$, not $\otimes$.
completeness: [Clément et al. 22]
simplified: [Heurtel 25]

Equational theory

$$(\text{Sum}) \quad \alpha \quad \beta = \alpha + \beta$$

$$(2\pi) \quad \textcircled{2\pi} = \boxed{}$$

$$(H^2) \quad \text{---} H^{(i,i+1)} \text{---} H^{(i,i+1)} \text{---} = \text{---}$$

$$(\text{XH}) \quad \text{---} X^{(i,j)} \text{---} H^{(j,k)} \text{---} = \text{---} H^{(i,k)} \text{---} X^{(i,j)} \text{---}$$

$$(\text{EH}) \quad \text{---} H^{(i,j)} \text{---} \textcircled{j} \text{---} H^{(i,j)} \text{---} \textcircled{j} \text{---} H^{(i,j)} \text{---} = \text{---} \textcircled{j} \text{---} H^{(i,j)} \text{---} \textcircled{i} \text{---} \textcircled{j} \text{---} H^{(i,j)} \text{---} \textcircled{j} \text{---}$$

$\alpha_0 \qquad \alpha_2 \qquad \beta_0 \qquad \beta_1 \qquad \beta_2 \qquad \beta_3$

$$(3\text{Rx}) \quad \text{---} R_X^{(b,d)}(\gamma_1) \text{---} R_X^{(d,c)}(\gamma_2) \text{---} R_X^{(b,d)}(\gamma_3) \text{---} = \text{---} R_X^{(d,c)}(\delta_1) \text{---} R_X^{(b,d)}(\delta_2) \text{---} R_X^{(d,c)}(\delta_3) \text{---}$$

$$(\text{CXC}) \quad \text{---} \textcircled{c} \text{---} X^{(a,b)} \text{---} \textcircled{b} \text{---} X^{(c,d)} \text{---} \textcircled{c} \text{---} X^{(a,b)} \text{---} = \text{---} \textcircled{a} \text{---} X^{(c,d)} \text{---} \textcircled{d} \text{---} X^{(a,b)} \text{---} \textcircled{a} \text{---} X^{(c,d)} \text{---}$$

$$(\text{S}) \quad \text{---} \textcircled{a} \text{---} X^{(a,b)} \text{---} \textcircled{a} \text{---} X^{(a,b)} \text{---} \textcircled{a} \text{---} X^{(a,b)} \text{---} = \text{---} \text{---}$$

$(a,b) : 0 \leq a < b < d$

$$\text{notation: } \text{ctrl}_k(\theta) \equiv \boxed{P_k(\theta)}$$

Recovering the properties

Every exact equality has a QC_d -derivation

Theorem. For every finite dimension $d \geq 2$, the finite theory QC_d is **sound and complete** for exact unitary qudit circuits, including global phase.

exact: unitary equality, not approximation or noise

finite: fixed finite schemata for each d

local: bounded circuit windows inside contexts

Implications

- ▶ certificates for exact qudit rewrites
- ▶ explicit branch syntax
- ▶ gate equations separate from control algebra

Future work

- ▶ orient fragments as rewrite systems
- ▶ native and fault-tolerant gate sets
- ▶ arithmetic controls; fragment comparison
